

Day 3 Task Solution: Customer and Content Workflows

1 Customer Support Workflow

An effective customer support workflow automates the process of handling incoming inquiries. The process begins when a new email is received, which triggers the automation. The email's content is then classified to determine its nature (e.g., customer support query, spam). For legitimate support questions, an AI agent takes over. This agent accesses a dedicated knowledge base to find relevant information and then drafts a helpful, context-aware response. Finally, the drafted email is automatically sent back to the customer, ensuring timely and accurate support.

2 LinkedIn Content Creator Workflow

Automating content creation for platforms like LinkedIn can save significant time. This workflow can be initiated manually or set to run on a schedule. It starts by pulling a content topic from a spreadsheet. Next, it performs a web search using an external service to gather current information and articles related to that topic. An AI agent then uses this research to compose a well-written, engaging LinkedIn post. Once the post is created, the workflow updates the original spreadsheet with the new content, keeping your content calendar organized and up-to-date.

3 Tools Used

Several tools are essential for building these advanced workflows:

- **Gmail:** Used for both triggering workflows based on incoming emails and for sending automated responses.
- **Pinecone:** A vector database that acts as a specialized knowledge base for an AI agent, allowing for fast and relevant information retrieval.
- **n8n AI Agent:** The core component that uses AI models to make decisions, process information, and generate content.
- **Open Router:** A service that provides access to a wide variety of AI models, allowing you to choose the best one for a specific task.
- **Tavily:** A search API designed for AI agents, used to gather real-time information from the web.
- **Google Sheets:** Acts as a simple database for storing and retrieving structured data, such as content topics or contact lists.
- **HTTP Request Node:** A versatile node used to communicate with almost any web service or API that doesn't have a dedicated n8n node.
